

1-Dimensional Optimization

critical points
 $f'(x) = 0$

global minimizer

$$x^* \text{ s.t. } f(x^*) \leq f(x) \quad \forall x \in X$$

hard to determine

local minimizer

$$x^* \text{ s.t. } \exists \delta > 0 \text{ s.t. } f(x^*) \leq f(x) \quad \forall x \text{ s.t. } |x - x^*| < \delta$$

strong local minimizer

$$x^* \text{ s.t. } \exists \delta > 0 \text{ s.t. } f(x^*) \leq f(x) \quad \forall x \text{ s.t. } |x - x^*| < \delta$$

continuous

$$f'(x) = 0$$

$$f''(x) > 0 \Rightarrow \text{strong local minimum}$$

$$f'(x) = 0$$

FO NC

for a local minimum

$$f''(x) \geq 0$$

SONC

not sufficient for local minimum (inflection point)

Bracketing

1. Identify interval containing local minimum
2. Shrink interval

Property: Unimodality

A function f is unimodal if \exists unique optimizer x^* such that f is monotonically decreasing for $x \leq x^*$ and monotonically increasing for $x \geq x^*$

unimodal
and convex

not unimodal
and not convex

unimodal
not convex

not unimodal
convex

f unimodal \rightarrow bracketing finds a global minimum

Break:

unimodal function
have 3 function calls

how do you use the function calls
to shrink maximally
